- Second Evaluation

• • = • • = •

Legality is a key feature in most Polyhedral scheduling algorithms, but :

- Initially, the Legality constraints on the scheduling coefficients are non-linear constraints
- Farkas lemmal¹ is used to linearize the constraints
- New variables "Farkas multipliers" are therefore introduced to define the resulting linear system

¹ Julius Farkas. "Theorie der einfachen Ungleichungen.". In: Journal für die reine und angewandte Mathematik (Crelles Journal) 1902.124 (1902), pp. 1–27. DOI: doi:10.1515/crll.1902.124⊐1> < ♂ → < ≧ → < ≧ → < ≧ → <

Motivation

Carrying Farkas multipliers as part of the scheduling problem is problematic and inefficient :

- We do not care about their values
- They increase the number of variables in the linear system considerably:
 - The problem becomes Harder to solver for ILP solvers
 - Longer compilation time
 - Source of errors and risk of reliability

What is the best way to eliminate them ?!

Farkas multipliers elimination methods - FME

The idea of Fourier-Motzkin-Elimination:²

Given a system of inequalities with k + 1 variables, it possible to obtain a system with k variables with no alteration to the solution space (in \mathbb{R}^k).

However, our system involves equalities and inequalities.

 \rightarrow Many ways to handle the equalities $e_i = 0$:

- Naive : $e_i \ge 0 \bigwedge e_i \le 0$ 2n new inequalities
- Smart: $e_i \ge 0 \bigwedge \sum e_i \le 0$ n+1 new inequalities
- Leveraging the equalities to pre-eliminate some Farkas multipliers by applying a series of linear combinations.
 0 new inequalities

Farkas multipliers elimination methods - Cone Projection

Projection using Cones and Chernikova's algorithm:

It is possible to project Farkas multipliers from the system using polyhedra and cone representatios with $PolyLib^3$

- The constraints are translated from the Matrix form $AX \ge B|CX = D$ to Cone from using rays and vertices.
- The produced constraints are guaranteed to be minimal
- Chernikova's algorithms⁴ is used to assure the minimality $(O(n^3) \text{ complexity})$

Experimental setup

To determine which Farkas multipliers elimination method is the best:

- We evaluated the 5 Farkas Elimination methods Naive, Smart, Elimination, Fast_Elimination & ConeProjection on 7500 Kernels (extracted from Deep Learning models from MindSpore-Akg [2])
- 5 distinct ILP solvers were used to eliminate the solver bias [Piplib [6], Fpl [9], QiuQi, Cbc [7] & isl [10]]
- More than 200 000 executions were performed on a 32 cores Intel Xeon Silver 4215 CPU at 2.50GHZ
- In a Pluto⁵ style algorithm

Reliability and errors

Comparing the number of errors

- Cone_Projection is less reliable across all solvers
- FME variations are equally the most reliable

≣ 8 / 14

Global scheduling-time

Comparing global scheduling-time

- *Fast_Elimination* is the fast elimination method just slightly better.
- Cone_Projection is x3 to x9 slower than Naive.

Why and how ?

イロト イヨト イヨト

э

ILP time

ILP solving time

• The influence of the number of constraints generated by the different Farkas multipliers elimination methods is limited.

Farkas multipliers Elimination time

Farkas multipliers Elimination time

- The overhead of *Cone_Projection* makes is x20 slower than other methods
- Fast_Elimination > Smart > Elimination > Naive >> Cone_Projection

Tchoulak & Al.

Best Farkas Multipliers Elimination Method 11 / 14

э

Conclusion

- Pre-elimination of Farkas multipliers using explicit equalities and no *Cost function* is the best strategy for all solvers
- ConeProjection improves the ILP resolution time by 14% (because constraints are minimal) but the overhead is too high (x20 slower in Farkas Elimination) which makes is unusable in practice
- The Elimination method has very limited impact on ILP solving time (14% improvement with minimal constraints & 2% between FME variants)
- Optimizing Farkas multipliers Elimination method is key to achieve efficient scheduling-time.
